

I. INTRO TO C

Hello World

```
#include <stdio.h>
```

```
int main(void) {
    printf("Hello World!\n");
    return 0;
}
```

#include: preprocessor inserts `stdio.h` contents

stdio.h: contains `printf` declaration

main: program starts here

void: keyword for argument absence

{ }: basic block/scope delimiters

printf: prints to the terminal

\n: newline character

return: leave function, return value

Compiling

```
$ gcc hello.c -o hello
$ ./hello
Hello World!
```

Basic Data Types

```
char c = 5; char c = 'a';
    one byte, usually for characters (1970: ASCII is fine)
int i = 5; int i = 0xf; int i = 'a';
    usually 4 bytes, holds integers
float f = 5; float f = 5.5;
    4 bytes floating point number
double d = 5.19562
    8 bytes double precision floating point number
```

Basic Data Types – logic

```
int i = 5 / 2; //i = 2
    integer logic, no rounding
float f = 5.0f / 2; //f = 2.5f
    decimal logic for float and double
char a = 'a' / 2 //a = 97 / 2 = 48
    char interpreted as character by console
```

Basic Data Types – signed/unsigned

```
signed int i = -5 //i = -5 (two's complement)
unsigned int i = -5 //i = 4294967291
```

Basic Data Types – short/long

```
short int i = 1024 //-32768...32767
long int i = 1024 //-2147483648...2147483647
```

Basic Data Types – more size stuff

```
sizeof int; sizeof long int; //4; 4; (x86 32-Bit)
    use data types from inttypes.h to be sure about sizes:

#include <inttypes.h>
int8_t i; uint32_t j;
```

Basic Data Types – const/volatile

```
const int c = 5;
    i is constant, changing it will raise compiler error
volatile int i = 5;
    i is volatile, may be modified elsewhere (by different program
    in shared memory, important for CPU caches, register, assump-
    tions thereof)
```

Variables – local vs. global

```
int m; // global variable

int myroutine(int j) {
    int i = 5 // local variable
    i = i+j;
    return i;
}
```

global variables (`int m`):

lifetime: while program runs

placed on pre-defined place in memory

basic block/function-local variables (`int i`):

lifetime: during invocation of routine

placed on stack or in registers

Variables – local vs. static

```
int myroutine(int j) {
    static int i = 5;
    i = i+j;
    return i;
}

k = myroutine(1); // k = 6
k = myroutine(1); // k = 7
```

static function-local variables:

saved like global variables

variable persistent across invocations

lifetime: like global variables

Printing

```
int i = 5; float f = 2.5;
printf("The numbers are i=%d, f=%f", i, f);
```

comprised of format string and arguments

may contain format identifiers (`%d`)

see also [man printf](#)

special characters: encoded via leading backslash:

```
\n newline
\t tab
\' single quote
\" double quote
\0 null, end of string
```

Compound data types

structure: collection of named variables (different types)

union: *single* variable that can have multiple types

members accessed via `.` operator

```
struct coordinate {
    int x;
    int y;
}
```

```
union longorfloat {
    long l;
    float f;
}
```

```
struct coordinate c;
c.x = 5;
c.y = 6;
```

```
union longorfloat lf;
lf.l = 5;
lf.f = 6.192;
```

Functions

encapsulate functionality (*reuse*)
 code structuring (*reduce complexity*)
 must be **declared** and **defined**
Declaration: states signature
Definition: states implementation (implicitly declares function)

```
int sum(int a, int b); // declaration
```

```
int sum(int a, int b) { // definition
    return a+b;
}
```

Header files

header file for frequently used declarations
 use **extern** to declare global variables defined elsewhere
 use **static** to limit scope to current file (e.g. **static float pi** in **sum.c**: no **pi** in **main.c**)

```
// mymath.h
int sum(int a, int b);
extern float pi;
```

```
// sum.c
#include "mymath.h"

float pi = 3.1415927;
int sum(int a, int b) {
    return a+b;
}
```

```
// main.c
#include <stdio.h>
#include "mymath.h"

void main() {
    printf("%d\n", sum(1,2));
    printf("%f\n", pi);
}
```

Data Segments and Variables

Stack: local variables
Heap: variables created at runtime via **malloc()**/**free()**
Data Segment: static/global variables
Code: functions

Function overloading

no function overloading in C!
 use arrays or pointers

Pointers

```
int a = 5;
int *p = &a // points to int, initialized to point to a
int *q = 32 // points to int at address 32
int b = a+1;
int c = *p; // dereference(p) = dereference(&a) = 5
int d = (*p)+2 // = 7
int *r = p+1; // pointing to next element p is pointing to
int e = *(p+2) // dereference (p+2) = d = 7
```

Pointers – linked list

linked-list implementation via next-pointer

```
struct ll {
    int item;
    struct ll *next;
}

struct ll first;
first.item = 123;

struct ll second;
second.item = 456;
first.next = &second;
```

Arrays

= fixed number of variables *continuously laid out in memory*

```
int A[5]; // declare array (reserve memory space)
A[4] = 25; A[0] = 24; // assign 25 to last, 24 to first elem
char c[] = {'a', 5, 6, 7, 'B'} // init array, length implicit
c[64] = 'Z' // NO bounds checking at compile/run (may raise
           protection fault)
```

// declare pointer to array; address elements via pointer:

```
char *p = c;
*(p+1) = 'Z'; p[3] = 'B'; char b = *p; // = 'a'
```

Strings

= array of **chars** terminated by **NULL**:

```
char A[] = { 'T', 'e', 's', 't', '\0' };
char A[] = "Test";
```

declaration via pointer:

```
const char *p = "Test";
```

common string functions (**string.h**):

length: **size_t strlen(const char *s, size_t maxlen)**

compare:

```
int strcmp(const char *s1, const char *s2, size_t n);
```

```
copy: int strcpy(char *dest, const char *src, size_t n);
```

tokenize: **char *strtok(char *str, const char *delim);**
 (e.g. split line into words)

Arithmetic/bitwise operators

arithmetic operators:

```
a+b, a++, ++a, a+=b, a-b, a--, --a, a-=b, a*b, a*=b, a/b, a/=b, a%b,
a%=b
```

logical operators:

```
a&b, a|b, a>>b, a<<b, a^b, ~a
```

difference pre-/post-increment:

```
int a = 5;
if(a++ == 5) printf("Yes"); // Yes
a = 5;
if(++a == 5) printf("Yes"); // nothing
```

operators in order of precedence:

```
( ), [ ], -, .
!, ++, --, +y, -y, *z, &=, (type), sizeof
*, /, %
+, -
<<, >>
<, <=, >, >=
==, !=
&
^
|
&&
||
?, :
=, +=, -=, *=, /=, %=, &=, ~=, =, <=, >=
,
```

Structures

brackets only needed for multiple statements

if/else, **for**, **while**, **do-while**, **switch**

may use **break/continue**

switch: need break statement, otherwise will fall through

```
if(a==b) printf("Equal") else printf("Different");
for(i=10; i>=10; i--) printf("%d", i+1);
int i=10; while(i-->0) printf("foo");
int i=0; do printf("bar"); while(i++ != 0);
```

```
char a = read();
switch(a) {
    case '1':
        handle_1();
        break;
    default:
        handle_other();
        break;
}
```

Type casting

explicit casting: precision loss possible

```
int i = 5; float f = (float)i;
```

implicit casting: if no precision is lost

```
char c = 5; int i = c;
```

pointer casting: changes address calculation

```
int i = 5; char *p = (char *)&i; *(p+1) = 5;
```

type hierarchy: „wider“/„shorter“ types

```
unsigned int wider than signed int
```

operators cast parameters to widest type

Attention: assignment cast after operator cast

C Preprocessor

modifies *source code* before compilation

based on preprocessor *directives* (usually starting with #)

```
#include <stdio.h>, #include "mystdio.h":
```

copies contents of file to current file

only works with strings in source file

completely ignores C semantics

Preprocessor – search paths

```
#include <file>: system include, searches in:
```

```
/usr/local/include
```

```
libdir/gcc/[target]/[version]/include
```

```
/usr/[target]/include
```

```
/usr/include
```

(target: arch-specific (e.g. i686-linux-gnu),
version: gcc version (e.g. 4.2.4))

```
#include "file": local include, searches in:
```

directory containing current file

then paths specified by `-i <dir>`

then in system include paths

Preprocessor – definitions

defines introduce replacement strings (can have arguments, based on string replacement)

can help code structuring, often leading to source code cluttering

```
#define PI 3.14159265
#define TRUE (1)
#define max(a,b) ((a > b) ? (a) (b))
#define panic(str) do { printf(str); for (;;) } while(0);
```

```
#ifdef __unix__
# include <unistd.h>
#elif defined _WIN32
# include <windows.h>
#endif
```

Preprocessor – predefined macros

system-specific:

```
__unix__, _WIN32, __STDC_VERSION__
```

useful:

```
__LINE__, __FILE__, __DATE__
```

Libraries

= collection of functions contained in object files, glued together in dynamic/static library

ex.: Math header contains declarations, but not all definitions

↪ need to link math library: `gcc math.c -o math -lm`

```
#include <math.h>
#include <stdio.h>

int main() {
    float f = 0.555f;
    printf("%f", sqrt(f*4));
    return 0;
}
```

II. INTRODUCTION TO OPERATING SYSTEMS

What's an OS?

abstraction: provides abstraction for applications

manages and hides hardware details

uses low-level interfaces (not available to applications)

multiplexes hardware to multiple programs (*virtualisation*)

makes hardware use efficient for applications

protection:

from processes using up all resources (*accounting, allocation*)

from processes writing into other processes memory

resource managing:

manages + multiplexes hardware resources

decides between conflicting requests for resource use

strives for efficient + fair resource use

control:

controls program execution

prevents errors and improper computer use

↪ **no universally accepted definition**
